Content

1. Description of search strategy	3
2. Description of included treatments.....	24
3. Risk of Bias assessment	26
4. Network Plots for Secondary Outcomes	29
5. Results of Network and Pairwise Meta-analyses of Secondary Outcomes	35
6. Cumulative Ranking Curves (Rankograms) for All Outcomes	44
7. Evaluation of Heterogeneity and Inconsistency	55
7.1 Heterogeneity	55
7.2 Consistency	55
7.3 Split of direct and indirect evidence for primary outcome	56
8. Alternative Pooling Analysis.....	58
9. Subgroup Analyses.....	60
9.1 Main analysis for positive symptoms	61
9.2 Subgroup analysis by number of sessions	62
9.3 Subgroup analysis by study duration.....	63
9.4 Subgroup analysis by setting.....	64
9.5 Subgroup analysis by therapist's expertise.....	65
9.6 Subgroup analysis by baseline severity	66
10. Sensitivity Analyses	67
10.1 Excluding open label studies	68
10.2 Excluding studies that presented only completer analyses.....	69
10.3 Excluding high risk of bias studies.....	70
10.4 Excluding studies with high risk of bias in researchers' allegiance	72
10.5 Excluding studies focused on treatment resistant patients	73
10.6 Excluding studies with a non-active comparison group	74
11. Investigation of Small Study Effects and Publication Bias	75
12. Evaluating the confidence in NMA	78
12.1 Summary of study limitations of the included studies	78
12.2 Contribution of comparisons to each network estimate by RoB	79
12.3 Table of reasons for downgrading.....	82
References	84

2. Description of included treatments

Acceptance and commitment therapy (ACT)	A manualized third generation behavioural therapy that incorporates acceptance and mindfulness-based strategies to help patients in overcoming negative thoughts and feelings.
AVATAR therapy (AVATAR)	People who hear voices create a computerised representation of the entity that they believed was the source of their main voice, and have then a dialogue with this digital representation (avatar) of their presumed persecutor. The avatar is voiced by the therapist, so that it responds by becoming less hostile and concedes power over the course of therapy.
Befriending* (Inactive Control)	Befriending involves engaging in conversation about everyday topics, whilst overtly avoiding discussion of symptoms and problems. The therapist aims to be empathic and nondirective, and psychotic or affective symptoms are not directly tackled in any way. The sessions focus on neutral topics, such as hobbies, sports, and current affairs.
Cognitive behavioral therapy (CBT)	Cognitive behavioural therapy for psychosis is usually based on an individualized case formulation and the establishment of collaborative goals with the patient. Therapy components include the improvement of existing coping strategies, the development and practice of new ones, the modification of delusional beliefs and beliefs about hallucinations and the challenge of dysfunctional schemas. Adaptive views of self are strengthened, including the re-evaluation of negative beliefs about the self.
Cognitive remediation*	A behavioural intervention aiming to improve cognitive processes. It used the 'Cognitive Remediation in Psychiatry Program' developed by 'HAPPYneuron', covering four cognitive domains (working memory, processing speed, verbal learning, reasoning and problem-solving). Modules are administered individually and accessible online.
Experience Focused Counselling (EFC)	EFC denotes aims at making sense of the voice-hearing experience within the person's life context and supporting the patient in learning to better deal with the experience as part of a recovery process. The intervention attempts to answer who and what problems the voices represent, also by uncovering traumatic life connections to voices.
Family intervention* (FI)	An intervention involving the relatives of the patient that may have a number of different aims. These include construction of an alliance with relatives who care for the person with schizophrenia, reduction of adverse family atmosphere, enhancement of the capacity of relatives to anticipate and solve problems, maintenance of reasonable expectations for patient performance, attainment of desirable change in relatives' behaviour and belief systems.
Hallucination Focused Integrative Treatment (HFIT)	This treatment integrates motivational interventions, training in coping skills, CBT, operant conditioning and single-family therapy with medication, psychoeducation, and rehabilitation.
Inactive Control* (IC)	Under this node we considered comparators conditions intended to control for non-specific aspects of the treatment, for example the time spent with the therapist (befriending, recreation and support, social activity therapy, supportive counselling)
Metacognitive Training (MT)	A group intervention whose aim is to make patients aware of their cognitive biases by helping them to reflect on various cognitive biases and their role in the formation and maintenance of psychopathology. Then patients are encouraged to discuss these biases and their implications with the help of real life examples and practical exercises. It is presumed that when the patients gain insight into their biases and relationship with psychopathology, they will challenge their beliefs and, thus, avoid the automatic cognitive traps.
Mindfulness (MF)	The intervention consists in guided meditation followed by reflective group discussion aimed at facilitating understanding, or metacognitive insight. During meditation, participants bring full awareness to difficult voices, feelings, thoughts and images, and also become aware of habitual coping reactions, safety behaviours and their effects. In meditation they practise letting go of these reactions and learn to allow and observe psychotic experiences come and go without reacting. Meditation and discussion lead to insight that struggling, judging and ruminating on psychotic experience creates distress, while mindful observation and acceptance of psychotic experience is empowering and calming.
Psychoeducation*	Psychoeducation may be defined as the education of a person with psychiatric disorder in subject areas that serve the goals of treatment and rehabilitation. With schizophrenic patients it covers the following topics: symptoms of psychosis, models of psychosis, effects and side-effects of medication, maintenance medication, early symptoms of relapse, relapse prevention.
Recreation and support* (Inactive Control)	The patients receive matched hours of therapist input providing structured activities and informal support. This consists mainly of flexible and low key leisure and social activities, ranging from the availability of a quiet room to listen to music, to outings and social groups.
Social activity therapy* (Inactive Control)	It consists in a program aimed at helping participants to identify activities they enjoyed and helping them to carry these out.
Social skills training* (SST)	Social skills training is an intervention for acquiring skills necessary to live in the community. It includes teaching skills such as symptom management and relapse prevention, involving role-plays, problem solving, in vivo exercises and home assignments. The therapists are instructed to model appropriate interaction styles and behaviors, and to teach clients how to effectively use the skills by using repetition and encouragements.
Supportive counselling* (Inactive Control)	This treatment is matched in terms of therapy time to the experimental arm. It aims to control for non-specific aspects of therapy by delivering basic assessment, psychoeducation and counselling in a supportive, warm, genuine, empathic and unstructured style. General counselling skills are used to maximise the non-specific effects of intervention.
Supportive Therapy* (ST)	A group active intervention, aimed at the provision of a safe and supportive atmosphere in which to raise issues of emotional importance to the patients, with an emphasis on the non-specific factors of warmth, empathy and genuineness. Patients have the opportunity to describe the narrative of their lives, including the impact of the illness, so that they can be helped to make sense of the timing of the illness and its nature and content with reference to strong and 'unbearable' affect regarding past aspects of personal history.
Treatment as usual (TAU)	Patients continue to receive standard psychiatric care. This can vary in the different settings according to national and local service protocols and guidelines, but usually includes regular psychiatric consultations, maintenance antipsychotic medication, out-patient and community follow-up, and access to community-based rehabilitative activities such as day centres and drop-in centres.

Waitlist (WL)	<p>Patients assigned to the waiting list group usually continue to receive treatment as directed by the referring practitioner. At the conclusion of the trial, the control group is offered the possibility to undertake the same intervention as the experimental group.</p> <p>By signing an informed consent to the trial, the patients know which the treatments arms are. As a result, when they do not start a new treatment, they know they have been assigned to the waiting list group; they know an intervention likely to be effective exist, and will be provided to them in the future. This condition is known to be associated with nocebo effect (patients might get worse).</p>
---------------	---

*not a treatment of interest for this review. Was used in included studies as comparator for an experimental intervention that we include

4. Network Plots for Secondary Outcomes

The network plots show the eligible comparisons for each outcome. Nodes represent the available treatments and edges represent the available comparisons. Both nodes and edges are weighted according to the number of studies involved in each treatment or comparison respectively. For outcomes in which the network was not connected, separate networks and comparisons are presented (in this case network plots were produced with STATA 14). Very less data were reported on the outcomes Relapse, Adverse events and Mortality due to specific reasons, so it was not meaningful to conduct any kind of analysis.

eFigure 11. Network plot for the secondary outcome Mortality for any reason

5. Results of Network and Pairwise Meta-analyses of Secondary Outcomes

We present here for each outcome league tables with network evidence in the lower triangle, and direct (pairwise) evidence in the upper triangle. Treatments are ranked by the surface under the cumulative ranking probabilities (eAppendix 6). Significant results are represented in bold. Data are SMDs (95% CIs) (for continuous outcomes) and RRs (95% CIs) (for dichotomous outcomes) in the column defining treatment compared with the row defining treatment. SMDs lower than 0 and RRs lower than 1 favour the column defining treatment. According to Cohen's guideline for magnitude of effect (1) SMDs of -0.2 can be considered small, -0.5 medium, and -0.8 large. To obtain SMDs for comparisons in the opposite direction, negative values should be converted into positive values, and vice versa. To obtain RRs for comparisons in the opposite direction, reciprocals should be taken.

Very less data were reported on the outcomes Relapse, Adverse events and Mortality due to specific reasons, so it was not meaningful to conduct any kind of analysis.

Abbreviations:

ACT = Acceptance and commitment therapy

AVATAR = AVATAR therapy

CBT = Cognitive behavioral therapy

EFC = Experience Focused Counselling

FI = Family intervention

HFIT = Hallucination Focused Integrative Treatment

IC = Inactive control

MT = Metacognitive Training

MF = Mindfulness

SST = Social skills training

ST = Supportive Therapy

TAU = Treatment as usual

WL = Waitlist

6. Cumulative Ranking Curves (Rankograms) for All Outcomes

We present here the surface under the cumulative ranking curve (SUCRA) for each outcome and tables with the corresponding probability values. However, we did not interpret the resulting hierarchies, because of the small number of studies for most of the comparisons, and therefore the low power of the analyses. This limitation would make the interpretation of the hierarchies not recommendable. Rankograms were produced with STATA 14.

Abbreviations:

7. Evaluation of Heterogeneity and Inconsistency

7.1 Heterogeneity

We inferred the magnitude of heterogeneity by comparing the estimated τ^2 to empirical distributions of heterogeneity typically found in meta-analyses (2). Heterogeneity can be considered low when the estimated τ^2 is less than the 25% quantile of the empirical distribution, moderate for τ^2 between 25% and 50% quantile and high for τ^2 larger than the 50% quantile.

Outcome	Between study variance (τ^2)	Heterogeneity assessment
Positive symptoms	0.0512	<i>low to moderate</i>
Dropout	0	0
Overall symptoms	0.0649	<i>low to moderate</i>
Negative symptoms	0.0024	<i>low</i>
Response	0	0
Relapse	(no NMA)	-
Adherence-insight	0	0
Depression	0	0
Quality of life	(no NMA)	-
Functioning	0.0547	<i>low to moderate</i>
Adverse events	(no NMA)	-
Death	0	0

7.2 Consistency

We evaluated global consistency under the assumption of a full design-by-treatment interaction model, using the *decompose design* function in R package netmeta.

Outcome	Q	df	P value
Positive symptoms	9.96	9	0.3536
Dropout	6.15	9	0.7247
Overall symptoms	5.94	5	0.3125
Negative symptoms	2.65	5	0.7537
Response	0.50	3	0.9199
Relapse	(no NMA)	-	-
Adherence-insight	0	0	-
Depression	4.30	1	0.0381
Quality of life	(no NMA)	-	-
Functioning	1.77	2	0.4128
Adverse events	(no NMA)	-	-
Death	0.58	3	0.9015

df= degree of freedom

7.3 Split of direct and indirect evidence for primary outcome

As a test for local consistency, we used the *netsplit* function in R package *netmeta*, which evaluates the agreement between direct and indirect evidence for each comparison. We detected no significant inconsistency for any comparison ($P > 0.10$ for all comparisons). However only few studies were available per comparison, leading to a low power to detect inconsistency.

eTable 10. Difference between direct and indirect evidence by comparison

Comparison	Number of studies providing direct evidence	Direct evidence proportion	nma [95%-CI]	direct [95%-CI]	indir. [95%-CI]	Diff [95%-CI]	z	p-value

8. Alternative Pooling Analysis

In this analysis the active comparators that were not an intervention of interest for this review were pooled under the label Active control ("Cognitive remediation", "Psychoeducation", "Family intervention", "Supportive Therapy", "Social skills training"). The results do not substantially differ from the main analysis; only CBT shows a benefit in comparison to Active control, and the ranking of the treatments remains unchanged.

9. Subgroup Analyses

We present here for each outcome league tables with network evidence in the lower triangle, and direct (pairwise) evidence in the upper triangle. Treatments are ranked by the surface under the cumulative ranking probabilities (eAppendix 6). Significant results are represented in bold. Data are SMDs (95% CIs) (for continuous outcomes) and and RRs (95% CIs) (for dichotomous outcomes) in the column defining treatment compared with the row defining treatment. SMDs lower than 0 and RRs lower than 1 favour the column defining treatment. According to Cohen's guideline for magnitude of effect (1) SMDs of -0.2 can be considered small, -0.5 medium, and -0.8 large. To obtain SMDs for comparisons in the opposite direction, negative values should be converted into positive values, and vice versa. To obtain RRs for comparisons in the opposite direction, reciprocals should be taken.

Abbreviations:

ACT = Acceptance and commitment therapy

10. Sensitivity Analyses

Abbreviations:

ACT = Acceptance and commitment therapy

AVATAR = AVATAR therapy

CBT = Cognitive behavioral therapy

EFC = Experience Focused Counselling

FI = Family intervention

HFIT = Hallucination Focused Integrative Treatment

IC = Inactive control

MT = Metacognitive Training

MF = Mindfulness

SST = Social skills training

ST = Supportive Therapy

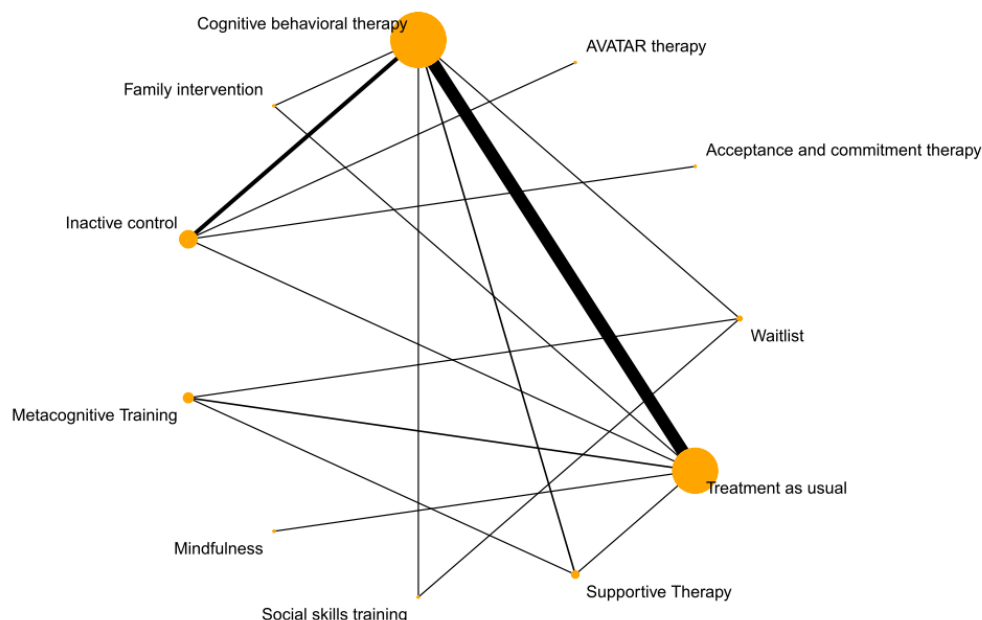

TAU = Treatment as usual

WL = Waitlist

10.1 Excluding open label studies

As sensitivity analysis, we excluded the open-label trials and performed pairwise and network meta-analysis for the primary outcome “Positive symptoms”. Overall 28 studies were included in the sensitivity analysis.

eFigure 24. Positive symptoms - excluding open label studies

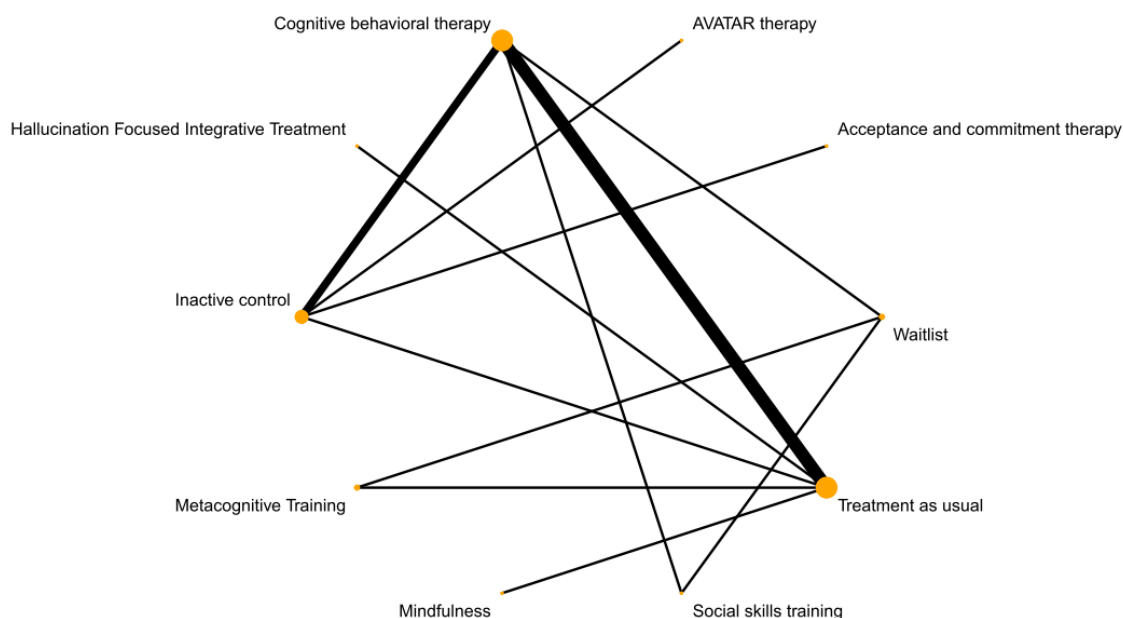

eTable 23. Positive symptoms - excluding open label studies. When only assessor-blind studies were considered, pairwise meta-analyses showed a benefit for CBT compared to TAU and for MT compared to ST. In network meta-analysis, AVATAR and CBT were superior to ST.

10.3 Excluding high risk of bias studies

As sensitivity analysis, we excluded the studies that presented an overall high risk of bias and performed pairwise and a network meta-analysis for the primary outcome “Positive symptoms”. A global score for Risk of Bias score was calculated according to the criteria proposed by Furukawa and colleagues (3): studies were classified as having overall high risk of bias if two or more domains were judged as high risk. For this aim, the item “Blinding of participants and personnel” was not considered, as they cannot be blind in studies on psychological treatments. The item “Researchers’ allegiance” was also not counted, since it is considered in a separate sensitivity analysis. Overall 31 studies were included in the sensitivity analysis.

eFigure 26. Positive symptoms - excluding high risk of bias studies

eTable 25. Positive symptoms - excluding high risk of bias studies. Excluding studies with a global score of high risk of bias, CBT was superior to TAU.

10.4 Excluding studies with high risk of bias in researchers' allegiance

As sensitivity analysis, we excluded the studies that were judged as high risk of bias for researchers' allegiance, and performed pairwise and a network meta-analysis for the primary outcome "Positive symptoms". Overall 6 studies were included in this sensitivity analysis.

eFigure 27. Positive symptoms - excluding studies with high risk of bias in researchers' allegiance

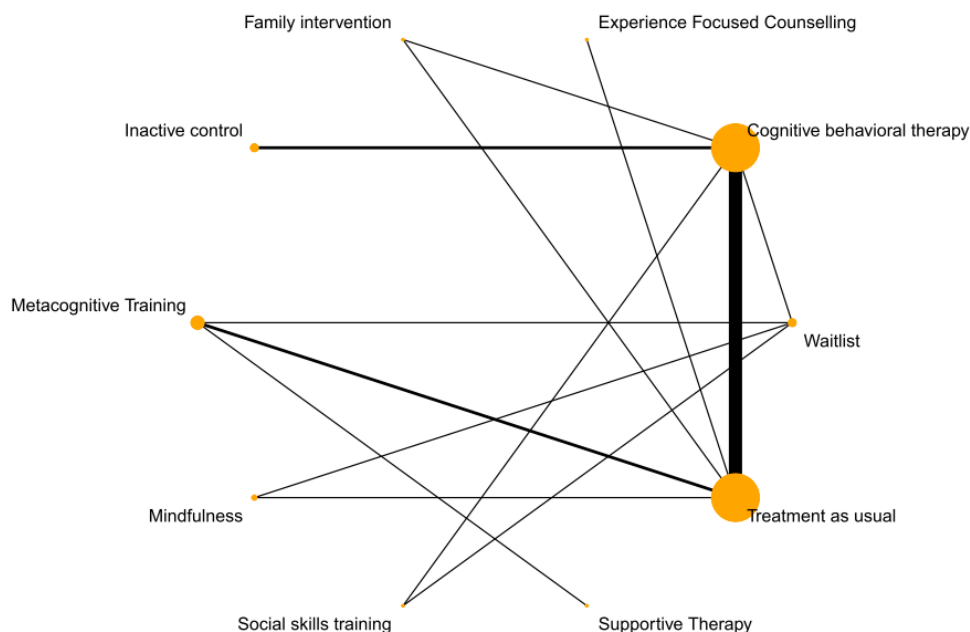

eTable 26. Positive symptoms - excluding studies with high risk of bias in researchers' allegiance. Excluding studies conducted by authors who developed the treatment under investigation, pairwise meta-analyses show a benefit for CBT in comparison with TAU and with WL (these results are confirmed in NMA), and for MT in comparison with ST. In NMA, CBT was superior to MT and ST, and TAU, WL and MT were superior to ST.

10.5 Excluding studies focused on treatment resistant patients

As sensitivity analysis, we excluded the studies that were focused on treatment resistant patients, as defined in the trials, and performed pairwise and a network meta-analysis for the primary outcome “Positive symptoms”. Overall 29 studies were included in this sensitivity analysis.

eFigure 28. Positive symptoms - excluding studies focused on treatment resistant patients

10.6 Excluding studies with a non-active comparison group

As sensitivity analysis, we excluded the studies that used a non-active comparison group, and performed pairwise and a network meta-analysis for the primary outcome “Positive symptoms”. For this analysis the studies Bechdolf 2004 and ACTRN12616000976482 were also considered (4, 5). Overall 7 studies were included in this sensitivity analysis.

eFigure 29. Positive symptoms - excluding studies with a non-active comparison group

11. Investigation of Small Study Effects and Publication Bias

We first examined funnel plot of pairwise meta-analysis with 10 or more studies included, since the power of tests for funnel plot asymmetry is considered very low when less than ten comparisons are included in the meta-analysis (6). The only pairwise meta-analysis including more than 10 studies was CBT versus TAU (18 studies). Visual inspection of the forest plot may suggest that some small studies favoring the TAU might be missing from the analysis. However Egger's test (which quantifies the bias captured by the asymmetry of the funnel plot and whether it is significant) do not reveal a significant asymmetry in the funnel plot ($t = 0.13$, $df = 16$, $p\text{-value} = 0.89$). As a further check, we applied Duval and Tweedie's trim and fill procedure (7), which yields an estimate of the effect size after the publication bias has been taken into account. The resulting effect size is an SMD of -0.30 (95 % CI -0.42 , -0.18), which is very similar to the original one.

eFigure 30. Funnel plot of comparisons CBT vs TAU. Grey circles represent identified studies, white circles represent potentially missing studies, whose effect has been estimated with trim and fill method.

eFigure 31. Contour-enhanced funnel plot of comparisons CBT vs TAU.

We also applied a comparison adjusted forest plot (8), specifically developed for NMA. Comparisons have been defined as newer versus older. Visual inspection of the funnel plot suggests that small studies that did not show a benefit for the newer psychological treatment over the older treatment are underrepresented in our data (possibly remain unpublished).

12. Evaluating the confidence in NMA

12.1 Summary of study limitations of the included studies

We evaluated the quality of evidence of primary outcome based on the Grading of Recommendations Assessment, Development and Evaluation (GRADE) framework, adapted to network meta-analysis (9). We assessed the following five domains for confidence in specific pairwise and network meta-analyses: Study limitations, Indirectness, Inconsistency, Imprecision and Publication bias. For this purpose, we also used the under-development online tool Confidence in Network Meta-Analysis (CINeMA) (10).

eFigure 33. Network plot with colours for Study limitations. The colours in the circles indicate the percentages of low RoB studies [green], moderate RoB studies [yellow] and high RoB studies [red] involving each intervention. The colours of the line indicate the RoB assessment of each comparison based on the above information - low RoB comparison [green], moderate RoB comparison [yellow] and high RoB comparison [red].

12.2 Contribution of comparisons to each network estimate by RoB

Based on the above assessment of RoB for each comparison and the contribution matrix detailing contribution of each direct comparison to all network estimates, the following bar graphs show the percentage of low, moderate or high RoB contributions for each network estimate.

eFigure 34. Contribution bar graph. Each bar corresponds to a NMA relative treatment effect and shows how much information comes from comparisons at low risk of bias [green], moderate risk of bias [yellow] or high risk of bias [red].

12.3 Table of reasons for downgrading

Comparison	Nature of the evidence	Confidence	Downgrading due to
ACT vs IC	Mixed	Moderate	Imprecision ³

Ranking of treatments		Low	Study limitations ² , Indirectness ⁵

1 Dominated by evidence at high risk of bias (> 50%).

2 Dominated by evidence at moderate risk of bias (> 50%).

3 Confidence interval includes values favouring either treatment (considering a margin of equivalence of 0.20).

4 There might be some concerns about heterogeneity between study variance in this comparison (prediction intervals extend into clinically important or unimportant effect, using a reference interval of 0.20).

5 Lack convincing evidence for the plausibility of the transitivity assumption due to few studies included in the network
